Answer Set Programming

Answer set programming (ASP) is a form of declarative programming introduced by (Gelfond and Lifschitz 1988).

ASP has been successively used in many works:

- Constraint programming (Niemela 1999)
- Knowledge representation and reasoning (Baral 2003/2008)
- Multi-agent systems (Nieuwenborgh et al. 2006)

Motivation

Our interest is to **help the construction** of efficient ASP based reasoning systems.

Example (For a Developer: Modeling)

The **indivisible nature** of ASP programs is causing increasing difficulties as program instances tend to grow in real applications.

Example (For an ASP based System: Reasoning)

Reactivity of an ASP based system is very dependant on the quantity of knowledge, i.e. size of the program, used for reasoning.

Proposal: design pattern

What we propose is a **design pattern** to model reasoning by multiple ASP programs.

Our idea is quite similar to (Minsky 1991):

Is a mind composed of smaller and smaller minds, until the pieces become so small that they are no longer mind like?

Proposal: design pattern

What we propose is a **design pattern** to model reasoning by multiple ASP programs.

Example (Modeling)

It is usually easier to model a system as a set of small interacting components rather than a huge and obscure monolithic system.

Proposal: Framework

A **framework** to reason by combinations of ASP programs.

Example (Reasoning)

Modular division of ASP programs can allow to reduce the quantity of knowledge used for reasoning.

Theory and Observation Modules

We first propose to separate background knowledge and observations.

Theory Module

- Background knowledge
- Given

Observations Module

- Consistent observations
- Acquired

Module Combination

The core idea of our reasoning framework is similar to **contextual logic programming** (Monteiro and Porto 1989).

Modules combination

Module Combination

The core idea of our reasoning framework is similar to **contextual logic programming** (Monteiro and Porto 1989).

Modules combination

- My moves possibilities

We define a reasoning system consisting of independent logic programs which can be combined together regarding context needs.

Module Combination

The core idea of our reasoning framework is similar to **contextual logic programming** (Monteiro and Porto 1989).

Modules combination

- My moves possibilities
- Wolves moves possibilities

We define a reasoning system consisting of independent logic programs which can be combined together regarding context needs.

Module Combination

The core idea of our reasoning framework is similar to **contextual logic programming** (Monteiro and Porto 1989).

Modules combination

- My moves possibilities
- Wolves moves possibilities
- My safe moves

We define a reasoning system consisting of independent logic programs which can be combined together regarding context needs.

Module Combination

The core idea of our reasoning framework is similar to **contextual logic programming** (Monteiro and Porto 1989).

Modules combination

- My moves possibilities
- Wolves moves possibilities
- My safe moves
- Actions to run away

We define a reasoning system consisting of independent logic programs which can be combined together regarding context needs.

Combination and Meta-Knowledge

These programs combinations can be known by the agent as meta-knowledge about its own knowledge.

Meta-knowledge

- Movements

In our module typology we use meta-knowledge module to represent knowledge about module combination (dotted circle).

Combination and Meta-Knowledge

These programs combinations can be known by the agent as meta-knowledge about its own knowledge.

Meta-knowledge

- Movements
- My moves

In our module typology we use meta-knowledge module to represent knowledge about module combination (dotted circle).

Combination and Meta-Knowledge

These programs combinations can be known by the agent as meta-knowledge about its own knowledge.

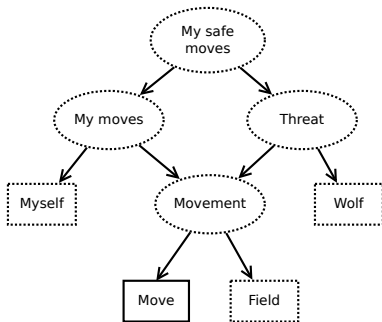

Meta-knowledge

- Movements
- My moves
- Threat

In our module typology we use meta-knowledge module to represent knowledge about module combination (dotted circle).

 - **Keywords**
 - Evaluation
- 4 Summary
 - Contribution and Outlook

Keywords

Our framework parses ASP programs and answer set to interpret respectively two simples keywords:

- *include('module name')*

Movements

```
%#include " Move".  
%#include " Field".
```

Keywords

Our framework parses ASP programs and answer set to interpret respectively two simples keywords:

- *include('module name')*
- *next('module name')*

Survive

```
%#include "Wolf".  
%#extern position/2.
```

```
wolf :- position(wolf,Position).  
next("Hunted") :- wolf.  
next("Hunter") :- not wolf.
```

Knowledge Division

In this example, we propose a possible division of the reasoning of a rabbit agent into 4 independent parts.

Empty arrows represent **inclusions**, plain ones represent **decisions**.

Experiments

Experimental application based on the survival game example. Arrows represent some movements that agents are considering in order to explore/feed/hide/escape.

Results

Reasoning time evolution regarding number of observations.

Experimental results, for each method it shows rabbit reasoning time average of 1000 runs.

- 4 Summary
 - Contribution and Outlook

Contributions

- Contributions
 - A **design pattern** to represent knowledge as multiple ASP programs.
 - A **framework** to use this representation within an ASP based reasoning system.
- Outlook
 - Dynamic **learning** of module and combinations
 - Experiment based
 - Generic methods to **divide** a monolithic ASP program
 - Rules dependency
